

Instrument Information Sheet (Tear Sheet) — Format & Examples

■■ **EDUCATIONAL / ILLUSTRATIVE ONLY.** The instruments, figures, and recommendations below are **hypothetical**, built to mirror the format a research/trading desk uses. **Not investment advice.** No live data.

A **tear sheet** is the one-page brief a desk produces per instrument: the snapshot metrics, the view, the catalysts/risks, and — the part most retail tools omit — a **specific derivative recommendation** with strikes, cost, and payoff. This doc gives the **reusable template** plus two worked examples (an equity and a commodity). It doubles as the **target output spec** for the Trader Screener's per-instrument detail view.

THE TEMPLATE (what every sheet contains)

[illegible]

The discipline: **thesis** → **metrics that support it** → **a structure whose payoff matches the thesis and the volatility regime**. A bullish view in *high* IV is expressed differently (spread) than the same view in *low* IV (outright call).

EXAMPLE 1 — EQUITY TEAR SHEET (hypothetical)

Northwind Semiconductor — NWS · Equity · Semiconductors

Date: illustrative · **Rating:** BUY · **12-mo target:** \$240 (+20% vs \$200 spot)

Snapshot

Metric	Value	Metric	Value
Price	\$200	Avg daily \$ vol	\$1.8B (deep)
Market cap	\$310B	Beta	1.35
52-wk range	\$128 – \$214	Realized vol (30d)	34%
Fwd P/E	28×	ATR (14d)	\$6.20
EV/EBITDA	19×	IV / IV Rank	38% / 72 (elevated)
Upside to target	+20%	Skew	moderate put skew

Thesis

Structural AI-datacenter demand + a product cycle into next year. Momentum strong (above rising 50/200-day MAs, RS in top decile). **But IV Rank is high (72)** ahead of earnings — options are *rich*, so we want a structure that **doesn't overpay for volatility**.

Catalysts & risks

- **Catalysts:** earnings (≈3 wks), product launch, sector capex guides.
- **Risks:** earnings IV-crush, China export policy, high valuation (28× fwd) → sharp drawdown if growth disappoints.

Positioning / smart money

- Net **insider buying** last quarter (illustrative); two committee-linked congressional buys flagged.
- **Unusual options activity:** upside call sweeps in the front month.

Technicals

- Uptrend; support \$188 (50-day), resistance \$214 (prior high); RSI 61 (room before overbought).

■ Derivative recommendation — Bull Call Spread

Long 205 call / short 225 call, ~3-month expiry · net debit \$7/share.

Metric	Value
Max profit	\$13/share (at $\geq \$225$)
Max loss	\$7/share (debit, at $\leq \$205$)
Breakeven	\$212
Greek bias	+delta, reduced vega (sells the rich upper strike)

Why this structure: bullish thesis, but **IV Rank 72 makes a lone long call expensive** (you'd overpay vega and get crushed post-earnings). Selling the 225 call offsets premium and caps vega — express the upside view at defined, lower cost. If IV Rank were *low*, we'd prefer an outright call.

EXAMPLE 2 — COMMODITY TEAR SHEET (hypothetical)

WTI Crude Oil — CL futures · Commodity · Energy

Date: illustrative · View: NEUTRAL-to-LONG, hedge downside · Use case: producer risk desk

Snapshot

Metric	Value	Metric	Value
Spot	\$78/bbl	Front-month OI	high / liquid
52-wk range	\$66 – \$94	Realized vol (30d)	41%
Contango/backwardation	mild backwardation	IV / IV Rank	44% / 65
Roll yield	positive (backwardation)	Skew	call-side (supply risk)

Thesis

A producer is **long physical crude** and wants to **protect a budget floor** without selling all upside. Near-term **backwardation + elevated IV (Rank 65)** mean selling an upside call is well-paid — fund a downside put with it.

Catalysts & risks

- **Catalysts:** OPEC+ meeting, inventory prints (EIA), geopolitics, demand data.
- **Risks:** demand shock (recession) → price collapse; supply shock → spike (caps capped upside).

Positioning

- Managed-money net length elevated; commercial hedgers adding shorts (illustrative COT read).

■ Derivative recommendation — Costless Producer Collar

Long crude + buy \$72 put / sell \$88 call, ~3-month expiry · ≈ \$0 net cost.

Metric	Value
Downside floor	–\$6/bbl (protected below \$72)
Upside cap	+\$10/bbl (gives up gains above \$88)
Net premium	≈ \$0 (call funds the put — works <i>because</i> IV/skew rich)

Effect	locks a \$72–\$88 realized band
--------	---------------------------------

Why this structure: the producer needs **certainty, not speculation**. A collar floors the downside; selling the rich upside call (high IV Rank) pays for it, so protection is ~free. Trade-off: capped gains above \$88. This is the **hedger** use-case from Harris's taxonomy — risk transfer, not a directional bet.

WHY THIS IS THE SCREENER'S TARGET OUTPUT

This tear sheet is essentially **what the Trader Screener's per-instrument detail view should generate**. Every block maps to data the project already has or plans to collect:

Tear-sheet block	Screener data source
Snapshot valuation/fundamentals	<code>fundamentals.json</code> , <code>model.json</code> (■ have)
Liquidity / ADV / beta / ATR	OHLCV-derived (■ free yfinance)
Options: IV, IV Rank, skew, term	options-chain feed (■ paid — shortlist \$2h)
Positioning / smart money	congress + insider + UOA (■ equity moat)
Technicals	OHLCV-derived (■)

Derivative recommendation	rules engine: thesis (score/momentum) × IV Rank → structure
----------------------------------	---

The recommendation logic = the "matching action to signal" table from the [Examples Gallery](#): bullish + low IV → long call; bullish + high IV → call spread; hedge + rich skew → collar; range + high IV → condor. A screener that fuses your **smart-money moat** with **IV-regime-aware structure selection** is the differentiated, firm-grade output — exactly the legitimacy gap discussed for the project.
