

## Instrument Information Sheet (Tear Sheet) — Format & Examples

■ ■ **EDUCATIONAL / ILLUSTRATIVE ONLY.** The instruments, figures, and recommendations below are **hypothetical**, built to mirror the format a research/trading desk uses. **Not investment advice.** No live data.

A **tear sheet** is the one-page brief a desk produces per instrument: the snapshot metrics, the view, the catalysts/risks, and — the part most retail tools omit — a **specific derivative recommendation** with strikes, cost, and payoff. This doc gives the **reusable template** plus two worked examples (an equity and a commodity). It doubles as the **target output spec** for the Trader Screener's per-instrument detail view.

## THE TEMPLATE (what every sheet contains)

[illegible]

The discipline: **thesis** → **metrics that support it** → **a structure whose payoff matches the thesis and the volatility regime**. A bullish view in *high* IV is expressed differently (spread) than the same view in *low* IV (outright call).

# EXAMPLE 1 — EQUITY TEAR SHEET (hypothetical)

## Northwind Semiconductor — NWS · Equity · Semiconductors

**Date:** illustrative · **Rating:** BUY · **12-mo target:** \$240 (+20% vs \$200 spot)

### Snapshot

| Metric           | Value         | Metric              | Value                      |
|------------------|---------------|---------------------|----------------------------|
| Price            | \$200         | Avg daily \$ vol    | \$1.8B (deep)              |
| Market cap       | \$310B        | Beta                | 1.35                       |
| 52-wk range      | \$128 – \$214 | Realized vol (30d)  | 34%                        |
| Fwd P/E          | 28×           | ATR (14d)           | \$6.20                     |
| EV/EBITDA        | 19×           | <b>IV / IV Rank</b> | <b>38% / 72</b> (elevated) |
| Upside to target | +20%          | Skew                | moderate put skew          |

### Thesis

Structural AI-datacenter demand + a product cycle into next year. Momentum strong (above rising 50/200-day MAs, RS in top decile). **But IV Rank is high (72)** ahead of earnings — options are *rich*, so we want a structure that **doesn't overpay for volatility**.

### Catalysts & risks

- **Catalysts:** earnings (≈3 wks), product launch, sector capex guides.
- **Risks:** earnings IV-crush, China export policy, high valuation (28× fwd) → sharp drawdown if growth disappoints.

### Positioning / smart money

- Net **insider buying** last quarter (illustrative); two committee-linked congressional buys flagged.
- **Unusual options activity:** upside call sweeps in the front month.

### Technicals

- Uptrend; support \$188 (50-day), resistance \$214 (prior high); RSI 61 (room before overbought).

## ■ Derivative recommendation — Bull Call Spread

Long 205 call / short 225 call, ~3-month expiry · net debit \$7/share.

| Metric     | Value                                              |
|------------|----------------------------------------------------|
| Max profit | <b>\$13/share</b> (at $\geq \$225$ )               |
| Max loss   | <b>\$7/share</b> (debit, at $\leq \$205$ )         |
| Breakeven  | <b>\$212</b>                                       |
| Greek bias | +delta, reduced vega (sells the rich upper strike) |

**Why this structure:** bullish thesis, but **IV Rank 72 makes a lone long call expensive** (you'd overpay vega and get crushed post-earnings). Selling the 225 call offsets premium and caps vega — express the upside view at defined, lower cost. If IV Rank were *low*, we'd prefer an outright call.

## EXAMPLE 2 — COMMODITY TEAR SHEET (hypothetical)

# WTI Crude Oil — CL futures · Commodity · Energy

Date: illustrative · View: NEUTRAL-to-LONG, hedge downside · Use case: producer risk desk

## Snapshot

| Metric                 | Value                    | Metric             | Value                   |
|------------------------|--------------------------|--------------------|-------------------------|
| Spot                   | \$78/bbl                 | Front-month OI     | high / liquid           |
| 52-wk range            | \$66 – \$94              | Realized vol (30d) | 41%                     |
| Contango/backwardation | mild backwardation       | IV / IV Rank       | 44% / 65                |
| Roll yield             | positive (backwardation) | Skew               | call-side (supply risk) |

## Thesis

A producer is **long physical crude** and wants to **protect a budget floor** without selling all upside. Near-term **backwardation + elevated IV (Rank 65)** mean selling an upside call is well-paid — fund a downside put with it.

## Catalysts & risks

- **Catalysts:** OPEC+ meeting, inventory prints (EIA), geopolitics, demand data.
- **Risks:** demand shock (recession) → price collapse; supply shock → spike (caps capped upside).

## Positioning

- Managed-money net length elevated; commercial hedgers adding shorts (illustrative COT read).

## ■ Derivative recommendation — Costless Producer Collar

Long crude + buy \$72 put / sell \$88 call, ~3-month expiry · ≈ \$0 net cost.

| Metric         | Value                                                          |
|----------------|----------------------------------------------------------------|
| Downside floor | –\$6/bbl (protected below \$72)                                |
| Upside cap     | +\$10/bbl (gives up gains above \$88)                          |
| Net premium    | ≈ \$0 (call funds the put — works <i>because</i> IV/skew rich) |

|        |                                 |
|--------|---------------------------------|
| Effect | locks a \$72–\$88 realized band |
|--------|---------------------------------|

**Why this structure:** the producer needs **certainty, not speculation**. A collar floors the downside; selling the rich upside call (high IV Rank) pays for it, so protection is ~free. Trade-off: capped gains above \$88. This is the **hedger** use-case from Harris's taxonomy — risk transfer, not a directional bet.

## EXAMPLE 3 — EQUITY, BEARISH (hypothetical)

### Overdrive Retail — OVR · Equity · Consumer Discretionary

**Date:** illustrative · **Rating:** SELL · **12-mo target:** \$125 (–17% vs \$150 spot)

#### Snapshot

| Metric           | Value              | Metric              | Value                       |
|------------------|--------------------|---------------------|-----------------------------|
| Price            | \$150              | Avg daily \$ vol    | \$420M                      |
| Fwd P/E          | 31× (vs peers 18×) | Beta                | 1.1                         |
| 52-wk range      | \$138 – \$205      | Realized vol (30d)  | 39%                         |
| Upside to target | –17%               | <b>IV / IV Rank</b> | <b>47% / 80</b> (very rich) |

## Thesis

Margins compressing as discount peers take share; valuation still priced for growth. Price broke below the 200-day MA. **IV Rank 80** → puts are expensive, so a *long* put overpays vega → use a **spread**.

## Catalysts & risks

- **Catalysts:** holiday sales data, guidance cut risk at earnings.
- **Risks (to the short):** short squeeze (high short interest), a takeover bid, a dovish macro turn lifting all retail.

## ■ Derivative recommendation — Bear Put Spread

Long 150 put / short 130 put, ~3-month · net debit \$7/share.

| Metric     | Value                                                                                      |
|------------|--------------------------------------------------------------------------------------------|
| Max profit | <b>\$13/share</b> (at $\leq \$130$ )                                                       |
| Max loss   | <b>\$7/share</b> (debit)                                                                   |
| Breakeven  | <b>\$143</b>                                                                               |
| Why        | bearish in <b>high IV</b> → the short 130 put funds the long, caps vega cost vs a lone put |

# EXAMPLE 4 — EQUITY, RANGE-BOUND / INCOME (hypothetical)

## Rangebound Utilities — RNG · Equity · Utilities

Date: illustrative · View: NEUTRAL (range \$93–\$107) · Goal: income

### Snapshot

| Metric         | Value        | Metric             | Value                           |
|----------------|--------------|--------------------|---------------------------------|
| Price          | \$100        | Beta               | 0.45 (low)                      |
| 52-wk range    | \$88 – \$112 | Realized vol (30d) | 16% (calm)                      |
| Dividend yield | 3.8%         | IV / IV Rank       | 24% / 78 (rich vs its own calm) |

### Thesis

Low-beta, rate-sensitive, **tends to mean-revert in a tight band**. No near-term catalyst. **IV Rank is high relative to its low realized vol** → option premium is overpriced for how little this name actually moves. **Sell** that premium, defined-risk.

### ■ Derivative recommendation — Iron Condor

**Sell 93/107 strikes, buy 88/112 wings, ~6-week · net credit \$1.60.**

| Metric     | Value                                                       |
|------------|-------------------------------------------------------------|
| Max profit | <b>+\$1.60</b> (price stays \$93–\$107)                     |
| Max loss   | <b>–\$3.40</b> (wing width – credit)                        |
| Breakevens | <b>\$91.40 / \$108.60</b>                                   |
| Greek bias | <b>–vega, +theta</b> — profits from time decay + falling IV |

## EXAMPLE 5 — EQUITY, EVENT / LONG VOLATILITY (hypothetical)

### Biocatalyst Therapeutics — BIO · Equity · Biotech

Date: illustrative · View: BIG MOVE, direction unknown · Event: trial readout

#### Snapshot

| Metric         | Value       | Metric              | Value                               |
|----------------|-------------|---------------------|-------------------------------------|
| Price          | \$50        | Catalyst            | Phase-3 readout (~4 wks)            |
| 52-wk range    | \$22 – \$78 | Realized vol (30d)  | 55% (high, but...)                  |
| Binary outcome | yes         | <b>IV / IV Rank</b> | <b>60% / 30</b> (low for this name) |

#### Thesis

A trial readout is **binary** — the stock gaps up on success or craters on failure; direction is genuinely unknown. Crucially **IV Rank is only 30** — the market hasn't yet fully priced the event, so volatility is **cheap relative to the move coming**. Buy volatility, not direction.

■ **Derivative recommendation — Long Straddle**

**Long 50 call + long 50 put, expiry after the readout · total premium \$4.**

| Metric     | Value                                                                           |
|------------|---------------------------------------------------------------------------------|
| Max profit | large (either tail)                                                             |
| Max loss   | <b>\$4</b> (both premiums)                                                      |
| Breakevens | <b>\$46 / \$54</b>                                                              |
| Greek bias | <b>+vega, -theta</b> — wants the move <i>and</i> rising IV; hurt by delay       |
| ■■ Risk    | <b>IV crush</b> — if the event resolves mildly, IV collapses and both legs lose |

**EXAMPLE 6 — ETF / PORTFOLIO HEDGE**  
**(hypothetical)**

# Broad-Market ETF — BMKT · Equity index ETF

Date: illustrative · View: LONG-TERM HOLD, hedge a drawdown · Use: portfolio insurance

## Snapshot

| Metric       | Value                            | Metric  | Value                             |
|--------------|----------------------------------|---------|-----------------------------------|
| Price        | \$500                            | Holding | core long position                |
| IV / IV Rank | 18% / 25 (low — cheap insurance) | Macro   | election + rate uncertainty ahead |

## Thesis

Keep the long-term holding, but **near-term tail risk** is elevated and **IV Rank is low** → protection is *cheap right now*. Buy insurance before fear is priced in (Harris: hedge before the adverse-selection premium widens).

## ■ Derivative recommendation — Protective Put

Long ETF + buy 480 put, ~3-month · premium \$8/share.

| Metric            | Value                                                     |
|-------------------|-----------------------------------------------------------|
| Max profit        | unlimited (the ETF's upside, less premium)                |
| Max loss          | <b>floored at −\$28/share</b> (below \$480)               |
| Cost of insurance | \$8/share (≈1.6%)                                         |
| Why now           | <b>low IV Rank = cheap puts</b> ; defined, known downside |

## The six examples in one table

| # | Instrument      | View                  | IV Rank   | Structure        | Why that structure                       |
|---|-----------------|-----------------------|-----------|------------------|------------------------------------------|
| 1 | NWS (equity)    | Bullish               | 72 (high) | Bull call spread | bullish but IV rich → cap vega cost      |
| 2 | WTI (commodity) | Hedge long            | 65 (high) | Costless collar  | sell rich call to fund put floor         |
| 3 | OVR (equity)    | Bearish               | 80 (high) | Bear put spread  | bearish in high IV → spread not lone put |
| 4 | RNG (equity)    | Neutral/range         | 78 (high) | Iron condor      | sell overpriced premium, defined risk    |
| 5 | BIO (equity)    | Big move, unknown dir | 30 (low)  | Long straddle    | buy cheap vol before a binary event      |

|   |            |              |          |                |                              |
|---|------------|--------------|----------|----------------|------------------------------|
| 6 | BMKT (ETF) | Hold + hedge | 25 (low) | Protective put | cheap insurance, low IV Rank |
|---|------------|--------------|----------|----------------|------------------------------|

***The through-line:** the **view sets the delta** (up/down/neutral/move), the **IV Rank sets the structure** (buy premium when low, sell/spread when high). Same rule, six situations.*

# WHY THIS IS THE SCREENER'S TARGET OUTPUT

This tear sheet is essentially **what the Trader Screener's per-instrument detail view should generate**. Every block maps to data the project already has or plans to collect:

| Tear-sheet block                 | Screener data source                                              |
|----------------------------------|-------------------------------------------------------------------|
| Snapshot valuation/fundamentals  | <code>fundamentals.json</code> , <code>model.json</code> (■ have) |
| Liquidity / ADV / beta / ATR     | OHLCV-derived (■ free yfinance)                                   |
| Options: IV, IV Rank, skew, term | options-chain feed (■ paid — shortlist \$2h)                      |
| Positioning / smart money        | congress + insider + UOA (■ equity moat)                          |
| Technicals                       | OHLCV-derived (■)                                                 |
| <b>Derivative recommendation</b> | rules engine: thesis (score/momentum) × IV Rank → structure       |

**The recommendation logic = the "matching action to signal" table** from the [Examples Gallery](#): bullish + low IV → long call; bullish + high IV → call spread; hedge + rich skew → collar; range + high IV → condor. A screener that fuses your **smart-money moat** with **IV-regime-aware structure selection** is the differentiated, firm-grade output — exactly the legitimacy gap discussed for the project.

*Related: [Derivatives — Types & Signals](#) · [Examples Gallery](#) · [Screener Shortlist](#). All figures herein are hypothetical and for education only.*
